ABSTRACT

Introduction Sexual dysfunction is a common complication in men with type 2 diabetes and is often refractory to treatment. This study investigated the long-term influence of the phosphodiesterase 5 inhibitor (PDE5) tadalafil on the level of sex hormones and sexual function in male Otsuka Long-Evans Tokushima Fatty (OLETF) rats as an animal model of spontaneous type 2 diabetes.

Research design and methods We treated 36-week-old male OLETF and non-diabetic Long-Evans Tokushima Otsuka (LETO) rats with oral tadalafil (100 µg/kg/day) for 12 weeks; sham groups received vehicle for 12 weeks. Before and after tadalafil treatment, serum levels of total and free testosterone, estradiol, luteinizing hormone (LH), follicle-stimulating hormone and proinflammatory cytokines were compared among four treatment groups. Copulatory function was examined by matching each rat to an estrous female. After completion of the experiment, total fat mass in the abdomen was measured.

Results Testosterone levels were significantly lower in OLETF versus LETO rats at 36 weeks. After 12 weeks of tadalafil treatment, levels of testosterone were significantly increased both in OLETF-tadalafil and LETO-tadalafil groups versus vehicle groups. Tadalafil decreased estradiol levels both in OLETF and LETO rats. Furthermore, tadalafil increased serum LH levels with a reduction of proinflammatory cytokines. Total fat mass was significantly lower in the OLETF-tadalafil group versus the OLETF-vehicle group. A significant suppression of copulatory behavior, that is, elongation of intromission latency was found in OLETF rats. However, tadalafil treatment for 12 weeks shortened the intromission latency.

Conclusion Our results indicate that tadalafil treatment might improve copulatory disorder in the type 2 diabetic model via improvement of an imbalance in sex hormones and an increase in LH levels.

INTRODUCTION

Increasing evidence has pointed to a relationship between the presence of type 2 diabetes and sexual dysfunction in men, an effect that has been shown to reduce quality of life.^{1,2} The ratio of erectile dysfunction (ED) in patients with diabetes is 1.9 to 5 times than that of subjects without diabetes, and it is reported

Significance of this study

What is already known about this subject?

- ▶ Sexual dysfunction in men with type 2 diabetes is sometimes resistant to phosphodiesterase 5 inhibitors therapy.
- ▶ Phosphodiesterase 5 inhibitors were suggested to increase testosterone levels in patients with erectile dysfunction.

What are the new findings?

- ▶ Copulatory behavior was suppressed, that is, elongation of intromission latency, in rats with type 2 diabetes.
- ▶ Long-term treatment with phosphodiesterase 5 inhibitor tadalafil corrected sex hormone imbalances (increased testosterone and decreased estradiol levels), leading to improved copulatory disorder.
- ▶ Tadalafil treatment increased serum luteinizing hormone levels with the reduction of proinflammatory cytokines and decreased total fat mass in the abdomen.

How might these results change the focus of research or clinical practice?

- ▶ The present results should encourage research on correcting imbalance of sex hormones for improving sexual dysfunction such as copulatory disorder, especially in men with type 2 diabetes.

that 35% to 90% of male patients with type 2 diabetes suffer from sexual dysfunction, including ED and diminished sexual desire.^{3,4} The decrease in sexual desire in men with type 2 diabetes has been suggested to be caused by male hypogonadism.⁵

Phosphodiesterase 5 inhibitors (PDE5Is) such as sildenafil, tadalafil, and vardenafil have been recommended for first-line treatment of ED and are also widely used for the treatment of ED caused by diabetes.^{6,7} However, sexual dysfunction in men with type 2 diabetes is sometimes resistant to PDE5I therapy.⁸ Compared with placebo, tadalafil

2.5 mg and 5 mg taken once daily over 12 weeks has been reported to lead to a significant improvement in International Index of Erectile Function (IIEF) erectile function, intercourse satisfaction, and overall sexual satisfaction domains in patients with diabetes, but not in sexual desire domain.⁹ The success rate of PDE5I treatment in men with type 2 diabetes has been reported to be significantly lower when compared with men without diabetes.¹⁰ Tadalafil 5 mg once daily was approved for the treatment of lower urinary tract symptoms suggestive of benign prostatic hyperplasia, and concomitant improvement of sexual function could be expected.^{11 12} PDE5Is were also suggested to increase testosterone levels in patients with ED even with on-demand use.^{13 14} Therefore, long-term use of a PDE5I may improve sexual desire via elevated testosterone levels. To the best of our knowledge, no studies have been performed regarding the effects of long-term treatment with tadalafil on sexual dysfunction, especially sexual desire, in men with type 2 diabetes.

The Otsuka Long-Evans Tokushima Fatty (OLETF) rat is an animal model of human type 2 diabetes.¹⁵ Male OLETF rats fed normal chow show obesity, hyperlipidemia, hypertension and late onset of hyperglycemia (after 18 weeks of age), which resemble those of human type 2 diabetes. The control strain, non-diabetic Long-Evans Tokushima Otsuka (LETO) rats is normal and never exhibits any components of diabetes.¹⁵ Although OLETF rats have ED with reduced level of serum testosterone,¹⁶ we expect that reduced testosterone will also result in copulatory behavioral disorders. In this study, we used OLETF rats as a model of type 2 diabetes and LETO rats as a control to investigate the effects of tadalafil on levels of testosterone, estradiol, luteinizing hormone (LH), follicle-stimulating hormone (FSH), and

proinflammatory cytokines as well its effects on sexual function, especially copulatory behavior.

MATERIALS AND METHODS

Animal preparation

Four-week-old male LETO and OLETF rats and female Sprague-Dawley rats purchased from Japan SLC (Shizuoka, Japan) were housed at a constant temperature of 23°C and 50% to 60% humidity under a regular 12 hours light/dark schedule at the University of Fukui Animal Center. We treated 36-week-old male OLETF and LETO rats with oral tadalafil (100 µg/kg/day) for 12 weeks; the sham groups received only vehicle for 12 weeks. We divided into six groups: LETO-36w, LETO-ve-48w, LETO-ta-48w, OLETF-36w, OLETF-ve-48w, and OLETF-ta-48w (LETO-36w, 36-week-old LETO rats; LETO-ve-48w, 48-week-old LETO rats treated with vehicle for 12 weeks; LETO-ta-48w, 48-week-old LETO rats treated with tadalafil for 12 weeks; OLETF-36w, 36-week-old OLETF rats; OLETF-ve-48w, 48-week-old OLETF rats treated with vehicle for 12 weeks; OLETF-ta-48w, 48-week-old OLETF rats treated with tadalafil for 12 weeks). Each group has eight rats. Tap water and standard rat chow were freely available. All animal experiments were performed in accordance with the guidelines established by the Fukui University Committee for Animal Experimentation.

Physiological and biochemical characteristics in LETO and OLETF rats

Mean body weight and systolic blood pressure (SBP) were monitored at the age of 36 and 48 weeks. SBP was measured in conscious rats with a computerized tail-cuff system (BA-98A System; Softron, Tokyo, Japan) that determines SBP using a photoelectric sensor. Plasma

glucose, triglycerides, cholesterol, and insulin levels were analyzed by SRL (Tokyo, Japan) at the age of 36 and 48 weeks.

Multiplex cytokines and hormone analysis

Free testosterone and total serum testosterone were measured at the age of 36 and 48 weeks by enzyme-linked immunoassay using the Rat Testosterone ELISA Kit and the Rat Free Testosterone ELISA Kit (Enzo Life Sciences International, New York, New York, USA) according to the manufacturer's instructions. Estradiol was measured by enzyme-linked immunoassay using the Estradiol ELISA Kit (Cayman Chemical, Ann Arbor, Michigan, USA) according to the manufacturer's instructions.

Serum concentrations of LH, FSH, interleukin-1 β (IL-1 β), IL-2, IL-4, IL-5, IL-6, IL-10, IL-13, interferon- γ (IFN- γ), monocyte chemoattractant protein-1 (MCP-1), tumor necrosis factor- α (TNF- α), and leptin of LETO and OLETF rats were evaluated using Milliplex MAP Kit (Millipore, Massachusetts, USA). Briefly, 25 μ L serum samples, standards, and quality controls were incubated with premixed antibody-immobilized beads for 2 hours in a shaker (TAITEC, Saitama, Japan). After washing, 25 μ L

biotin-labeled detection antibodies were added and incubated with for 1 hour, followed by 25 μ L of streptavidin-phycoerythrin incubation for 30 min. After washing again, the magnetic beads were resuspended in 150 μ L of sheath fluid for 5 min. Concentrations of cytokines and hormones in serum samples were measured using Luminex 200 instrument (Luminex, Austin, Texas, USA).

Sexual behavior

Female Sprague-Dawley rats were used as stimulus females for copulation tests. Each female rat was given estradiol benzoate intramuscularly at a daily dose of 1 mg beginning 5 days before mating to induce estrus. A smear of vaginal mucus that was determined to be estrus was required for all female rats used in the study. We put estrus female rats into the cages of male rats one by one at 18:00 and recorded and evaluated the sexual activity for 12 hours at 36, 42, and 48 weeks of age. During the observation, the intromission latency, the mount frequency, and the intromission frequency were recorded. The intromission latency is the time from the introduction of the female until the first intromission. Prolonged latencies and

reduced frequency were indications of reduced sexual desire.¹⁷

Measurement of abdominal fat mass

After completion of the experiment, rats were sacrificed with an overdose of pentobarbital (60 mg/kg). The abdomen of the rat was dissected and the weight of total fat mass in the abdomen was measured.

Statistical analysis

Results are presented as means \pm SEM. All data were analyzed by two-way analysis of variance using SPSS, V.16.0J for Windows. A p value < 0.05 was considered significant.

RESULTS

Metabolic analysis of LETO and OLETF rats

Body weight, plasma glucose levels, low-density lipoprotein (LDL)-cholesterol, and triglycerides were significantly higher in OLETF rats versus LETO rats at 36 weeks of age, and in OLETF rats versus LETO rats at 48 weeks (vehicle treated) of age (table 1). Treatment with tadafafil for 12 weeks significantly decreased plasma LDL-cholesterol and triglyceride levels in OLETF rats, but not in LETO rats.

Hormonal analysis

Total and free testosterone levels were significantly lower in LETO and OLETF rats at 48 weeks vs 36 weeks of age (figure 1A,B). However, estradiol levels were significantly higher in LETO and OLETF rats at 48 weeks vs 36 weeks of age (figure 1C). Twelve-week treatment with tadafafil increased total and free testosterone levels and decreased estradiol levels in both rat types (figure 1D-F). LH levels were significantly higher in LETO rats at 48 weeks compared with 36 weeks (figure 2C). In contrast, no significant differences in LH levels were seen in OLETF rats between these time points (figure 2A). FSH levels were significantly higher in LETO and OLETF rats at 48 weeks compared with 36 weeks irrespective of tadafafil treatment (figure 2B,D). Twelve-week treatment with tadafafil increased LH levels in OLETF rats ($p < 0.01$) (figure 2C).

Proinflammatory cytokine analysis

TNF- α levels were significantly higher in OLETF rats than those in LETO rats at 36 weeks of age (figure 3A). TNF- α levels of LETO rats did not change from 36 weeks compared with 48 weeks; however, levels in OLETF rats significantly increased over this time period. Twelve-week treatment with tadafafil significantly decreased the TNF- α levels of OLETF rats (figure 3B). Levels of other cytokines such as IL-1 β , IL-2, IL-6, MCP-1, IFN- γ , and leptin also increased with age and diabetes. However, levels of these cytokines decreased with 12-week treatment with tadafafil (data not shown). Levels of IL-4, IL-10 and IL-13 showed the opposite responses, that is, they decreased with age and diabetes and increased with 12-week treatment with tadafafil (data not shown).

Figure 3 Changes in tumor necrosis factor- α (TNF- α) after 12-week treatment with vehicle or tadafafil in LETO and OLETF rats at 36 weeks to 48 weeks of age (A) and at 48 weeks of age (B). ** $p < 0.01$ between values. LETO, Long-Evans Tokushima Otsuka; LETO-ta-48w, 48-week-old LETO rats treated with tadafafil for 12 weeks; LETO-ve-48w, 48-week-old LETO rats treated with vehicle for 12 weeks; LETO-36w, 36-week-old LETO rats; OLETF, Otsuka Long-Evans Tokushima Fatty; OLETF-ta-48w, 48-week-old OLETF rats treated with tadafafil for 12 weeks; OLETF-ve-48w, 48-week-old OLETF rats treated with vehicle for 12 weeks; OLETF-36w, 36-week-old OLETF rats.

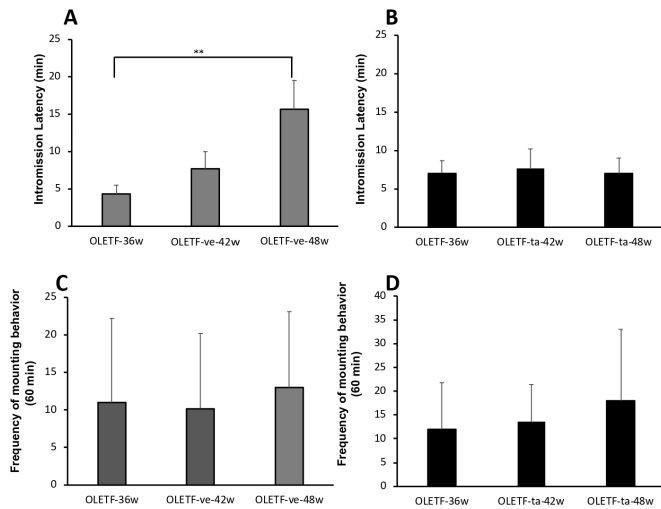

Figure 4 Changes in intromission latency (A, B) and frequency of mounting behavior (C, D) for 1 hour before and after 6 or 12 weeks treatment with vehicle (A, C) or tadalafil (B, D) in OLETF rats. ** $p < 0.01$ between values. OLETF, Otsuka Long-Evans Tokushima Fatty; OLETF-ta-42w, 42-week-old OLETF rats treated with tadalafil for 6 weeks; OLETF-ta-48w, 48-week-old OLETF rats treated with tadalafil for 12 weeks; OLETF-ve-42w, 42-week-old OLETF rats treated with vehicle for 6 weeks; OLETF-ve-48w, 48-week-old OLETF rats treated with vehicle for 12 weeks; OLETF-36w, 36-week-old OLETF rats.

Sexual behavior

Intromission latency was significantly higher in OLETF versus LETO rats at 36 weeks of age (LETO-36w: 4.0 ± 0.4 min; OLETF-36w: 8.1 ± 0.7 min; $p < 0.05$). Intromission latency increased from 36 weeks to 42 weeks, and 48 weeks of age in OLETF rats treated with vehicle (figure 4A). Significant increase in intromission latency was found between 36 and 48 weeks of age ($p < 0.01$). This finding represents suppression of mounting behavior. No significant change in intromission latency was found in LETO rats (LETO-ve-48w: 6.75 ± 2.6 min).

Intromission latency did not change from 36 to 48 weeks of age in OLETF rats treated with tadalafil (figure 4B). Twelve-week treatment with tadalafil prevented mounting ability from worsening. No change in frequency of mounting behavior was found after 12 weeks of treatment with vehicle or tadalafil (figure 4C,D).

Abdominal fat mass

LETO rats showed no increase in visceral fat weight at 48 weeks compared with 36 weeks of age (figure 5A). In contrast, OLETF rats showed a significant increase in visceral fat weight between 36 and 48 weeks of age ($p < 0.01$) (figure 5B). Twelve-week treatment with tadalafil significantly decreased visceral fat weight in both rats (both, $p < 0.01$).

DISCUSSION

OLETF rats fed normal chow showed obesity, hyperlipidemia, hypertension, and hyperglycemia with

Figure 5 Changes in visceral fat weight in LETO (A) and OLETF (B) rats. ** $p < 0.01$ between values. LETO, Long-Evans Tokushima Otsuka; LETO-ta-48w, 48-week-old LETO rats treated with tadalafil for 12 weeks; LETO-ve-48w, 48-week-old LETO rats treated with vehicle for 12 weeks; LETO-36w, 36-week-old LETO rats; OLETF, Otsuka Long-Evans Tokushima Fatty; OLETF-ta-48w, 48-week-old OLETF rats treated with tadalafil for 12 weeks; OLETF-ve-48w, 48-week-old OLETF rats treated with vehicle for 12 weeks; OLETF-36w, 36-week-old OLETF rats.

hypogonadism, which caused copulatory disorder. Oral administration of tadalafil for 12 weeks corrected sex hormone imbalances (increased testosterone and decreased estradiol levels) in OLETF rats, leading to improved copulatory disorder. Tadalafil treatment increased serum LH levels with the reduction of proinflammatory cytokines and decreased total fat mass in the abdomen. This study is the first to reveal the effects of PDE5I on copulatory disorder in rats with type 2 diabetes.

Epidemiological studies of men with type 2 diabetes have shown that hypogonadism is associated with sexual dysfunction, including ED and diminished sexual desire.^{18 19} Pathological animal models resembling hormonal dynamics of humans are necessary for pathological clarification and optimal treatment of sexual dysfunction in men with type 2 diabetes. OLETF rats are considered to be a model close to the natural history of type 2 diabetes in humans and have hyperinsulinemia and hypertension associated with obesity, and eventually changes from weight loss to low insulin.¹⁵ ED and copulatory dysfunction also appeared in the present study. Given this series of courses, it is considered to be suitable as a model for long-term administration of tadalafil. One study showed that testis weight decreased in OLETF rats compared with LETO rats, but no differences were found in testosterone or estradiol levels measured by a dextran-charcoal assay.²⁰ In contrast, bioavailable testosterone, which was measured by liquid chromatography-tandem mass spectrometry method, has been shown to be significantly lower in OLETF rats at 20 weeks of age compared with LETO rats.¹⁶ In the present study, total and free testosterone levels were significantly lower in OLETF rats

when compared with LETO rats at 36 weeks of age. These levels were measured by rat testosterone ELISA Kit and rat free testosterone ELISA kit. Therefore, it is speculated that differences in testosterone levels among rats of the same strain are due to different measurement methods.

Five-week testosterone replacement therapy (TRT) has been suggested to be effective for ED in OLETF rats by improving endothelial function and inflammation.¹⁶ TRT is widely used in patients with symptoms of hypogonadism, although it is not commonly used as a preventive intervention or for treatment for male patients with type 2 diabetes. There are some controversies regarding the use of TRT for hypogonadism associated with type 2 diabetes.^{21 22} TRT may cause side effects such as benign prostatic hyperplasia or cancer, cardiovascular risk due to increased red blood cells, and infertility. TRT should be used carefully with regular monitoring.

TRT was ineffective in improving ED in situations where serum levels of estradiol were high.²³ Estradiol induces ED by enhancing Rho-kinase-mediated smooth muscle contraction. Therefore, increases in serum testosterone levels have the potential to improve erectile function of male patients with diabetes as long as serum estradiol levels are kept low. After the 12 weeks of tadalafil treatment in this study, levels of total and free testosterone increased both in OLETF and LETO rats. Furthermore, tadalafil treatment decreased levels of estradiol. The shortened intromission latency as a sign of copulatory function in this study was likely the result of the improvement in the imbalance between serum testosterone and estradiol. There are some reports that ED occurs when the balance between testosterone and estradiol is lost.²³ However, no reports could be found on sexual behavior such as copulatory function.

Sexual dysfunction includes erectile, ejaculatory, and copulatory dysfunction. There are many reports that intromission latency, mount frequency are useful as parameters of copulatory function. Social stress has been reported to induce marked suppression of copulatory behavior, for example, elongation of intromission in male rats.¹⁷ Transplantation of interstitial cell suspension containing hormone-producing cells facilitates a restoration of copulatory activity, resulting in reduced intromission latency.²⁴ In this study, the intromission latency was significantly higher in OLETF rats than in LETO rats, indicating that OLETF rats had copulatory dysfunction. Male copulatory behavior is based on sexual desire (libido), which depends on the presence of testosterone.^{25 26} A decrease in serum testosterone levels is thought to cause copulatory dysfunction. Clinically, on-demand administration of flexible dosages of tadalafil (5, 10, and 20 mg) in men has been reported to induce significant decreases in serum estradiol levels with a significant increase in the testosterone/estradiol ratio, although total and free testosterone did not change.²⁶ Furthermore, 3-month treatment with tadalafil 5 mg once daily increased serum testosterone levels and was effective for ED in men caused by low testosterone

levels due to metabolic syndrome.²⁷ Therefore, tadalafil itself does not improve the copulatory disorder or increase sexual desire, but rather increases testosterone levels, which leads to improved copulatory function in the present study. As a result, it is possible that tadalafil treatment may prevent sexual activity from worsening in men with type 2 diabetes.

Several findings may explain why tadalafil treatment increases testosterone levels. Immunohistochemistry and western blotting analysis confirmed that PDE5I is localized in Leydig and peritubular cells of the rat testis, as well as in vascular smooth muscle cells.²⁸ Chronic treatment with sildenafil for 1 month increased cyclic guanosine monophosphate and promoted cholesterol uptake into the mitochondria of Leydig cells in male Swiss Webster mice. The accumulation of cyclic guanosine monophosphate could be involved in the stimulation of androgen biosynthesis in Leydig cells.²⁹

In the present study, increases in serum testosterone levels with tadalafil were associated with decreases in serum estradiol levels and total fat mass. Another study showed that treatment with PDE5I sildenafil 100 mg/day for 12 weeks reduced waist circumference and improved visceral adiposity in male patients with type 2 diabetes.³⁰ A recent report indicated that acute exposure to PDE5Is induced aromatase expression with an increase in estradiol concentrations in human visceral adipocytes.³¹ However, this observation does not explain the decrease in circulating estradiol levels in men with ED treated with long-term tadalafil.³² Using human osteoblast-like cells, it has been shown that tadalafil inhibits mRNA and protein expression of aromatase, which results in increases in testosterone levels in the supernatants.³³ Furthermore, tadalafil increased protein expression of androgen receptors and decreased estrogen receptors.³³ Long-term treatment with tadalafil might modulate aromatase activity, and this activity might be dependent on the target organs. Twelve-week treatment with tadalafil decreased the accumulation of visceral adipose tissue and improved hypertriglyceridemia in the rabbit by restoring insulin sensitivity and promoting differentiation of preadipocytes.³⁴ Furthermore, tadalafil has been shown to induce the expression of the brown fat-specific marker uncoupling protein 1 in visceral adipose tissue, leading to the conversion of white adipose tissue to brown adipose tissue.³⁴ The aromatase cytochrome P450 enzyme, which is responsible for a key step in the biosynthesis of estradiol, is highly expressed in white adipose tissue.³⁵ It is surmised that tadalafil decreases aromatase activity by changing white adipose tissue to brown adipose tissue.

A positive relationship was suggested between chronic inflammation or a proinflammatory state and obesity in animal models.^{36 37} White adipose tissue produces a large number of inflammatory factors including proinflammatory cytokines, such as IL-1 β , IL-6, and TNF- α , which are associated with insulin resistance.³⁷ In contrast, reducing inflammation in obese subjects has been shown to improve insulin resistance.³⁸ Furthermore,

proinflammatory cytokines have been found to influence the hypothalamic–pituitary–gonadal axis.³⁹ An increase in circulating TNF- α levels directly inhibits LH excretion from the pituitary gland, which results in decreased serum testosterone levels.⁴⁰ As shown in the present study, 12-week treatment with tadalafil slightly improved glucose intolerance and increased serum testosterone and LH levels with a reduction of proinflammatory cytokines. In diabetic mice, 1-month treatment with tadalafil also reduced circulating proinflammatory cytokines such as TNF- α and IL-1 β .⁴¹ Therefore, long-term treatment with tadalafil may improve sexual activity in patients with type 2 diabetes through its effects on the gonadal organs, adipose tissue, and pituitary gland. The increase in testosterone levels in the present study may be due to inhibitory effects of tadalafil on proinflammatory cytokines and resulting increases in LH, in addition to its direct effect on the testis. The lifespan of a rat is about 96 weeks. The dosing period corresponds to one-eighth, 10 years of a human life (80 years). Therefore, it corresponds to administration from the age of 40 to 50 years. Tadalafil requires long-term administration to improve copulatory disorders in patients with type 2 diabetes. Further investigations are necessary to explore the target organ of PDE5I related to increases in testosterone levels.

Limitations

This study has several limitations. First, measurement of the aromatase activity of the adipose tissue could not be carried out. Therefore, the cause of the decrease in estradiol levels could not be identified. Second, it is an animal study and results may not apply to humans.

CONCLUSIONS

In conclusion, type 2 diabetes might induce an imbalance of sex hormones, resulting in sexual dysfunction such as copulatory disorder. Treatment with the PDE5I tadalafil for 12 weeks was associated with an increased testosterone/estradiol ratio and improved copulatory function. Tadalafil also has the potential to increase serum LH levels, reduce proinflammatory cytokines, and decrease total abdominal fat mass.
